SPECIFICATION

To all whom it may concern:

Be It Known, That We, **Sean Christopher Erickson, a citizen of the United States of America, residing at 2918 Sagebrush Drive, Fort Collins, Colorado 80525 and Jonathan Alan Shaw, a citizen of the United States of America, residing at 5025 Sawhill Drive, Fort Collins, Colorado 80528, and Jay Tatsuo Fukumoto, a citizen of the United States of America, residing at 2831 Zendt Drive, Fort Collins, Colorado 80526** have invented certain new and useful improvements in **"High Performance Voltage Control Diffusion Resistor"**, of which We declare the following to be a full, clear and exact description:

BACKGROUND OF THE INVENTION

1. Technical Field:

The present invention relates generally to an improved circuit system and in particular to a resistor. Still more particularly, the present invention relates to a high-precision voltage controlled diffusion resistor.

2. Description of the Related Art:

A resistor is an electrical device that may convert energy into heat. The letter R is used to denote the resistance value of a resistor. With this device, two possible reference choices are present for the current and voltage at the terminals of the resistor. One is current in the direction of the voltage drop across the resistor and another is the current in the direction of voltage rise across the resistor.

Some existing problems with respect to resistors include transmission line impedance mismatching, the physical size required for diffusion resistors, and process variation in diffusion resistors. Currently, existing solutions for these problems include special Microwave Integrated Circuit (MIC) processes to make trimmed resistors. Further, high-precision discrete components are attached by soldering or bonding components to an integrated circuit (IC) or package. These currently used solutions are expensive with respect to the manufacturing of semiconductors.

This type of process involves using a laser to trim the resistors. The resistance is measured and a laser is used to reduce the size of the resistor. This type of process requires much time and is expensive to perform on a per circuit basis. Further, these existing solutions are difficult to integrate into a silicon IC process because of the size of components and/or specialized manufacturing requirements needed to trim the devices. Further, discrete or trimmed components are not adjustable after the manufacture of a product.

Therefore, it would be advantageous to have an improved diffusion resistor that overcomes the problems of the existing solutions.

LSI DOCKET NO. 03-1091

SUMMARY OF THE INVENTION

The present invention provides a diffusion resistor that is formed in the substrate. A diffusion region is formed within the substrate that contains a first and second contact region.

5 These contact regions extend downward from the surface of the substrate. A third contact is located within the diffusion region between the first and second contacts. This contact also extends downward from the surface of the substrate. These contacts are connected to metal layers. The first and second contacts form the two ends of the diffusion resistor. The third contact forms a Schottky diode such that application of a voltage to this contact forms a

10 depletion region within the diffusion region. The depletion region changes in size depending on the voltage applied to the third contact to change the resistance of the depletion resistor.

LSI DOCKET NO. 03-1091

BRIEF DESCRIPTION OF THE DRAWINGS

The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself however, as well as a preferred mode of use, further objects and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

Figure 1 is a cross-section of a voltage controlled diffusion resistor in accordance with a preferred embodiment of the present invention;

Figure 2 is a cross-section of a non-salicided version of a diffusion resistor in accordance with a preferred embodiment of the present invention;

Figures 3A-3D are diagrams illustrating cross-sections in processing steps for creating a voltage controlled diffusion resistor in accordance with the preferred embodiments of the present invention; and

Figure 4 is a schematic diagram of a radio frequency (RF) driver or receiver circuit with RF feedback in accordance with a preferred embodiment of the present invention.

DETAILED DESCRIPTION

The present invention provides for an improved diffusion resistor that is voltage controlled. The illustrative embodiments of the present invention take advantage of the fact that a Schottky diode is created when a metal comes into contact with a lightly doped semiconductor. The depletion layer that results in the metal to semiconductor contact may be used in conjunction with a voltage bias on a Schottky diode to reduce or increase the effective resistance of a diffusion resistor.

The structure of a high-precision voltage controlled diffusion resistor in the illustrative embodiments of the present invention includes a low mobility diffusion region with a positive contact at one end and a negative contact at the opposite end. A center tap is present consisting of the Schottky diode, formed by a metal to low mobility diffusion contact. The negative and positive contact regions are typical ohmic contacts.

Depending on the particular embodiment, a salicided region may be used at the contact interface while in another illustrative embodiment, only a metal contact is present. The resistance is made variable in these depicted examples through providing an ability to tune the resistor through a voltage controlled contact (VCC). This contact is located at about center of the resistor structure in these examples. Since the contact acts as a Schottky diode, a depletion layer is created at the VCC interface, which partially depletes the thickness of the diffusion resistor by a selected distance. The total conduction thickness may be changed by altering the depletion thickness through biasing the VCC contact. Through changing the depletion thickness, the total conduction thickness may be changed. As a result, an increase or decrease in effective resistance in the structure is created depending on the particular voltage applied to the VCC contact. In this manner, an ability to vary the resistance of the diffusion resistor through a voltage bias is accomplished.

The illustrative embodiments of the present invention provide for a reduction in physical resistor size. The reduction in the conduction thickness provides for creating a resistor of a higher value in the same space as a diffusion resistor without the use of a Schottky contact. This advantage is accomplished in the depicted examples because the effective conduction thickness

LSI DOCKET NO. 03-1091

is reduced by " X_d ". A basic diffusion resistor has the same conduction thickness of " t ". In contrast, the diffusion resistor of the present invention using a VCC has a conduction thickness of " $t-X_d$ ". In these examples, the VCC may be tied to ground and an increase in the effective resistance still exists.

5 The processes, steps, and structures described below do not form a complete process flow for manufacturing integrated circuits. The present invention can be practiced in conjunction with integrated circuit fabrication techniques currently used in the art, and only so much of the commonly practiced process steps are included as necessary for an understanding of the present invention. The figures below represent cross sections of a portion of an integrated circuit during
10 fabrication and are not drawn to scale, but are drawn so as to illustrate the important features of the invention.

 With reference now to the figures and in particular with reference to **Figure 1**, a cross-section of a voltage controlled diffusion resistor is depicted in accordance with a preferred embodiment of the present invention. In this example, diffusion resistor **100** is formed within
15 region **102** in substrate **104**. Substrate **104** is a p-substrate or an insulator in these examples. Typically, a p-substrate is used in a CMOS process and an insulator is used in a silicon on insulator process (SOI). Region **102** is an n- diffusion region in these examples. Further, diffusion resistor **100** is surrounded by shallow trench isolation (STI) region **106**. As illustrated, n+ contact region **108** and n+ contact region **110** are formed within diffusion region **102**.
20 Contact **112** and contact **114** are formed on salicided regions **113** and **115**. Salicided region **113** is formed on n+ contact region **108**, and salicided region **115** is formed on n+ contact region **110**. These contacts are standard ohmic contacts formed by metal layers. Contact **112** in this example is a positive terminal for diffusion resistor **100**, while contact **114** forms a minus terminal for diffusion resistor **100**. Contact **116** is a voltage control contact (VCC) for a
25 Schottky diode. In this example, contact **116** is formed over salicided region **118**. Depending on the voltage bias applied to contact **116**, depletion region **120** is formed and may grow or shrink.

 As voltage is applied to contact **116**, depletion region **120** grows in size. In particular, x_d represents the depth of depletion region **120**. This value increases as voltage is applied to contact **116**. In this example, t represents the thickness of region **102** and also represents the

conductivity. The overall conductivity is $t - x_d$ in which the conductivity decreases as x_d increases with the size of depletion region **120**.

Turning next to **Figure 2**, a non-salicided version of a diffusion resistor is depicted in accordance with a preferred embodiment of the present invention. Diffusion resistor **200** is essentially identical to diffusion resistor **100** in **Figure 1**. As can be seen, diffusion region **202** is formed within substrate **204** and surrounded by STI region **206**. Within depletion region **202** are n+ contact region **208** and n+ contact region **210**. Contact **212** and contact **214** are formed over salicided regions **213** and **215**, which are formed over n+ contact regions **208** and **210**. Further, contact **216** is formed on region **202**. In this example, however, a salicided region is absent. As with diffusion resistor **100** in **Figure 1**, depletion region **218** is formed and may increase or decrease in size depending on the voltage bias applied to contact **216**.

Turning now to **Figures 3A-3D**, diagrams illustrating cross-sections in processing steps for creating a voltage controlled diffusion resistor are depicted in accordance with the preferred embodiments of the present invention. In **Figure 3A**, substrate **300** is a p-substrate or may be an insulator. Oxide regions **302** and **304** have been formed around n-diffusion region **306**. Further, resist sections **308** and **310** have been placed on the surface of the device. In this example, the cross-section represents the manufacturing of the n-diffusion resistor at a point after shallow trench isolation formation has occurred. An n-type dopant is implanted into the device. In this example, the dopant may be, for example, phosphorous or arsenic. The implant is performed to result in a low concentration of n-type dopants. These dopants in these examples have a concentration of about 1×10^{15} per cm^3 . The doping profile of n-diffusion region **306** may be tuned in these examples to reduce parasitic capacitance.

In **Figure 3B**, photo resist sections **311**, **312**, and **314** have been formed over the device. This formation of these sections is typically formed by laying a photo resist layer and removing sections through selected development of the resist layer. Next, an n-type dopant is implanted into the device to form n+ contact region **316** and n+ contact region **318**. This implant step is performed to result in a high concentration of n-type dopants in the contact regions. Typically, the concentration may range from 1×10^{18} per cm^3 to 1×10^{20} per cm^3 .

In **Figure 3C**, resist regions **320** and **322** are formed on the device. Thereafter, salicided

LSI DOCKET NO. 03-1091

regions **324**, **326**, and **328** are formed. These regions are formed by deposition of a refractory metal followed by a rapid thermal anneal process. In the depicted examples, formation of these regions may be blocked depending on the particular implementation or processing used. By avoiding the creation of these salicided regions, the effect of the Schottky diode is enhanced.

5 However, blocking formation of these regions complicates the typical processing of the device. Therefore, depending on the particular implementation, the salicided regions may remain. A salicided contact region is more common in CMOS devices. These regions are used to increase the effect of resistance of the device. The refractory metal used for salicided regions **324**, **326**, and **328** is typically titanium or cobalt.

10 In **Figure 3D**, interlayer dielectric regions **330**, **332**, **334**, and **336** are formed. These regions are formed by creating a single dielectric layer and then selectively etching the layer to form contact regions. The deposition of a refractory metal into the contact regions forms contacts **338**, **340**, and **342**. In these examples, the length “l” and the thickness “t” are designed to be minimized to maximize the effect of the voltage effect on the resistor. These contacts are
15 typically formed using tungsten.

Turning now to **Figure 4**, a schematic diagram of a Rf driver or receiver circuit with RF feedback is depicted in accordance with a preferred embodiment of the present invention. In these examples, the RF feedback employs a variable resistor, such as the variable resistor in the illustrated examples. In this example, circuit **400** includes current source **402**, transistor **404**,
20 resistor **406**, and resistor **408**. In these examples, resistor **406** is a R_d resistor connecting transistor **404** to ground. Current source **402** has one end connected to transistor **404** and another end connected to voltage source VDD. Further, transistor **404** and current source **402** are connected to Vout. Vin is connected to the gate of transistor **404** and resistor **408**. In these examples, resistor **408** is a variable diffusion resistor as illustrated in the depicted examples.

25 Thus, the present invention in the illustrated examples provides for an adjustable or tunable resistance value in a diffusion resistor. The absolute value of the resistor in these examples may be modified with a voltage bias on the metal contact of the Schottky diode. By changing the voltage bias, the thickness of the resistor may be increased or decreased. With this feature, impedance matching adjustment for radio frequency (Rf) driver/receiver circuits may be

LSI DOCKET NO. 03-1091

made. The voltage controlled diffusion resistor in the illustrated examples allows for adjustment of the resistor value R_{in} for a receiver application or R_{out} for a driver application to match the transmission line impedance. In this manner, unwanted voltage reflections and signal loss are reduced or eliminated.

5 Further, adjustments to resistance allow for a bias current adjustment for mixed signal circuits. Also, the reduction in the size of the resistor is accomplished by reducing the resistor thickness. Additionally, resistance values may be self-adjusting through various circuit design techniques, such as implementing a feedback circuit with the resistor of the present invention. Further, the variable resistance value may be adjusted to compensate for process variations to
10 provide for uniform resistance. Also, the variable resistance may be adjusted to a very high resistance to put an analog circuit in a low current or low power sleep mode.

 The description of the preferred embodiment of the present invention has been presented for purposes of illustration and description, but is not intended to be exhaustive or limited to the invention in the form disclosed. Many modifications and variations will be apparent to those of
15 ordinary skill in the art. The embodiment was chosen and described in order to best explain the principles of the invention the practical application to enable others of ordinary skill in the art to understand the invention for various embodiments with various modifications as are suited to the particular use contemplated.
